DEGLI STUDI
FIRENZE

Python Tools Powering the GW Science Stack

- Python is currently the most widespread computing language in Gravitational Wave Astronomy, especially within the LVK
- It is the preferred language for Data Analysis pipelines
- Most tutorials, publications, and repositories (e.g., [GWOSC](#), Zenodo, the next tutorials) are written in Python
- Public alerts and parameter estimation reports are generated using Python-based tools

Key Python Libraries:

- [PyCBC](#): Matched filtering, SNR analysis, inspiral waveform generation
- [GWpy](#): Time series and spectrogram analysis tailored to LIGO data
- [Bilby](#): Bayesian inference for compact object mergers
- [ligo.skymap](#): Skymap generation and localization
- [Astropy](#): Collection of software packages for use in Astronomy
- [Python Virgotools](#): Functions to interact with the Virgo interferometer's software, hardware, and data.

Operations White Paper – OPS-8.5

Python is recommended for development to maximize compatibility with existing tools, reducing duplication-of-effort and redundancy.

Why Python has become Critical

Ecosystem Integration

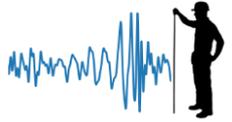

- Python easily integrates with:
 - **C/C++** (via bindings like [SWIG](#) or [ctypes](#)), still vital for performance-heavy components (e.g., [LALSuite](#) core)
 - **Shell scripts** (`subprocess`) for job management and automate workflows on computing clusters
 - **Web APIs** (Application Programming Interfaces, using `requests` module)
- Used to glue together workflows on computing clusters and notebooks alike:
 - Python scripts manage **job submission**, **data transfer**, and **pipeline execution**

Rapid Prototyping and Collaboration-Friendly

- Scientists write test scripts, visualizations, and simulations quickly with Python
- Ideal for collaborative work and reproducibility
- Rich ecosystem of open-source tools (Jupyter, GitHub, Conda, etc.)
- Huge online support community: [Stack Overflow](#), [forums](#), [GitHub Python](#), etc.

Python & Object-Oriented Programming

Minimal Introduction for Gravitational-wave Enthusiasts

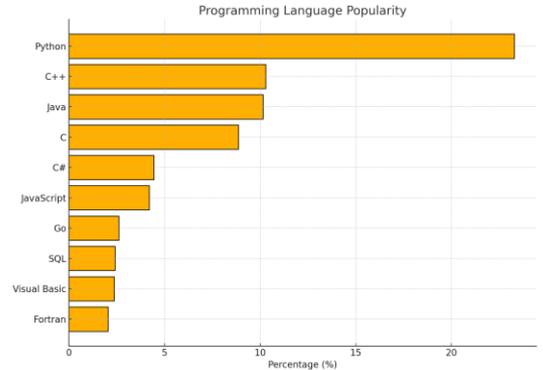

What is Python?

- Created in the late 1980s by Guido van Rossum (after Monty Python)
- [High-level](#), readable language, great for beginners or as a “first language”
- [Interpreted](#): runs line-by-line

What is Object-Oriented Programming (OOP)?

- A way of thinking about programs as **collections of objects**: Objects = data + behavior
- Helps organize and reuse code like we organize real-world things:
 - **Class** – A blueprint or template (e.g., “a car”)
 - **Object** – An instance of a class (e.g., “a Toyota Yaris Hybrid”)
 - **Attributes** – Characteristics of a Class (e.g., “white”, “115 CV”)
 - **Methods** – Actions by objects (e.g., “clean”, “refuel”)

Python Basics with a GW Twist

Key Concepts:

- Variables store data (e.g., event name, mass)
- Functions perform actionsencapsulate physics (e.g. Schwarzschild radius)

Code Example:

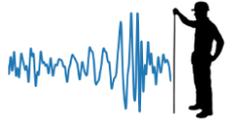

```
# Variables (this is a line comment BTW!)
name = "GW150914" # string
mass = 30 # in solar masses
spin = 0.7 # dimensionless spin

# Function
def schwarzschild_radius(m):
    """Function to return the Schwarzschild
    radius of a mass expressed in Solar Masses.

    And this is a block comment BTW (docstring)"""
    return 2 * m * 1.476 # km

print(f"Primary component mass of event {name}:")
print(schwarzschild_radius(mass))
```

OOP to Model Astrophysical Objects

Key Concepts:

- OOP is about classes (blueprints) and objects (instances): parallel with physical modeling
- **Class:** a type of thing (e.g., BlackHole)
- **Object:** an instance (e.g., bh1 = BlackHole(...))
- **Attributes:** mass, spin
- **Methods:** things it can do (e.g., merge)

Code Example:

```
# Class
class BlackHole:
    def __init__(self, mass, spin):
        self.mass = mass
        self.spin = spin

    def __str__(self):
        return f"BlackHole(mass={self.mass},
                    spin={self.spin})"
```

Contents:

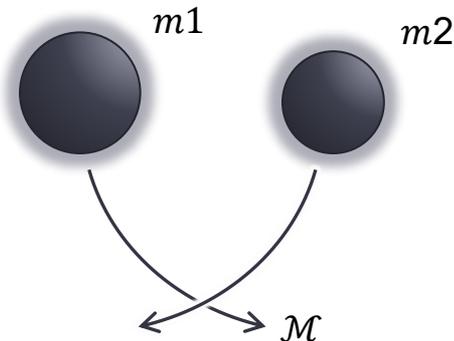

- `__init__` creates the object
- `self.mass, self.spin` are attributes
- `__str__` defines how it prints

Simulating Mergers with OOP and Methods

New concepts:

- `merge()` is a method that interacts with another object
- `Coalesce` is a result class
- The *chirp mass* is calculated for these two objects coalescing

Code Example:

```
# Another class
class Coalescence:
    def __init__(self, bh1, bh2):
        self.total_mass = bh1.mass + bh2.mass
        self.chirp = self.total_mass ** (5/3)

class BlackHole:
    ...
    def merge(self, other):
        return Coalescence(self, other)

# Example:
bh1 = BlackHole(30, 0.7)
bh2 = BlackHole(25, 0.5)
gw = bh1.merge(bh2)
print(gw.chirp)
```

Why Use OOP for Science?

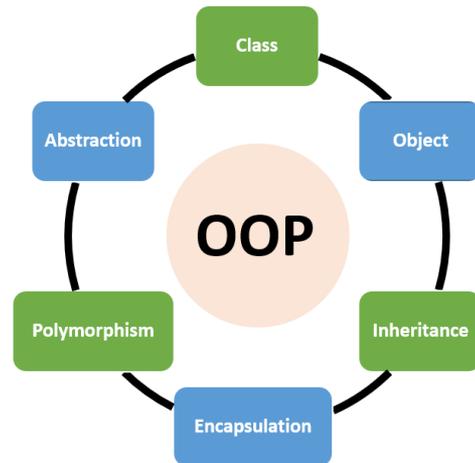

Benefits of OOP modeling:

- **Structure:** Keep code clean and modular
- **Reusability:** Use your BlackHole class in many contexts
- **Scalability:** Add features like position, velocity, collision_type
- **Intuition:** Think like a scientist, code like one

Extension Ideas:

- Create a `NeutronStar` class
- Add gravitational redshift method
- Simulate a population of black holes (which mass function?)
- Animate the chirp using [matplotlib](#) ([PyCBC](#) can come handy...)

What we will see next makes abundant use of OOP... Be prepared!

GWpy: Python Tools for GW Data Analysis

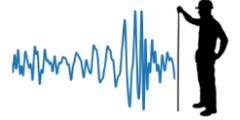

[GWpy](#) is Python package designed to simplify access, visualization, and manipulation of gravitational-wave time series and spectral data, developed for and by the LIGO/Virgo collaboration. It is supported by a thorough documentation and extensive list of examples available online.

Key Features:

- Read data from frame files, GWFs, or NDS servers
- Analyze time series (`TimeSeries`) and frequency series (`FrequencySeries`)
- Handles Data Quality flags (`DataQualityFlag`) and event lists, such as GW events, glitch triggers, etc. (`EventTable`)
- Extensive signal processing built-in functionalities
- Easily read open data (`TimeSeries.fetch_open_data()`)
- Generate publication-quality plots (via `matplotlib`): many of the plots that you see on LVK publications have been partly realized using the GWpy module

Conda Environments: Reproducible Research in a Box

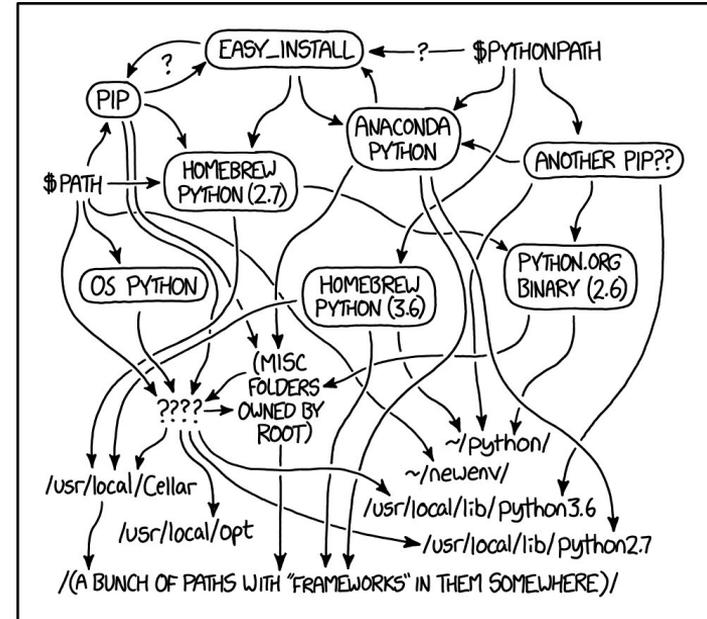

What is a [Conda](#) Environment?

- A self-contained software environment, includes Python, packages, libraries, and dependencies. Think of it as a virtual lab that's isolated from the rest of your system

Why Use It?

- Avoid conflicts between different projects (e.g., Python 3.9 for one, 3.11 for another)
- Set up **exactly the right software** for your analysis (and no more) with easy version control
- Portable and cross-platform (works on Linux, macOS, Windows)
- Makes it easy to share reproducible environments among collaborators
- Easily install or roll back packages.

MY PYTHON ENVIRONMENT HAS BECOME SO DEGRADED THAT MY LAPTOP HAS BEEN DECLARED A SUPERFUND SITE.

IGWN Conda: Ready-to-Go Tools for Gravitational Wave Analysis

An [IGWN Conda environment](#) is a curated set of conda environments developed by the **International Gravitational-Wave Network (IGWN)**. Already available on every IGWN computing centers.

Includes tools for LVK data analysis and software development:

- All the standard libraries, like: numpy, scipy, matplotlib, jupyter, pandas, etc.
- gwpy, ligo.skymap, pycbc, bilby, astropy, lal, gwdechar, gcc, root, etc.
- Up-to-date and tested in LVK workflows

Installation

```
conda install -c conda-forge igwn-py311
conda activate igwn-py311
```

Export/Share Your Env:

```
conda env export > env.yaml
conda env create -f env.yaml
```

Pro tip: Pinning Environments

Use pinned environments (e.g. igwn-py39-20230425) to ensure stability and avoid surprises during paper preparation or collaboration.

Avoid: Installing random pip packages inside Conda envs.

Keep environments small and task-specific.

Jupyter: Interactive Computing for Scientists

- [Jupyter](#) is an open-source project for interactive, literate programming
- Supports code + text + plots + outputs (images, audio, videos, etc.) in one document
- Originally from “JULia, PYthon, and R”. Now supports 40+ language
- Gives access to computing centers via Jupyter servers, including [CIT](#), [CC-IN2P3](#)
- Easy file transfer and directory navigation.

Ideal For:

- Developing, prototyping & debugging
- Tutorials, lectures and presentations
- Scientific reporting.

The screenshot shows a Jupyter Notebook window with the following content:

```
[1]: from IPython.display import YouTubeVideo
      YouTubeVideo("mgJfHs17qk", width=800, height=300)
```

[1]:

This is a crash course on how to access Virgo data and perform basic data analysis and detector characterization tasks from the machines at the EGO Computing Center.

In its style, this tutorial is similar to those of the [Open Data Workshops](#), which could be a useful reference and complement: [link to github repo](#).

Preliminary notions

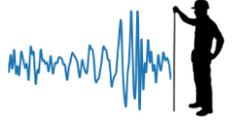

If you've made it this far, it means you know how to use the Linux command line and open a Jupyter notebook.

Now we will see how to use some Python packages to access Virgo data and perform simple data analysis operations.

GWOSC Tutorials

On the GWOSC website, many tutorials are available as Jupyter notebooks: [link](#).

Jupyter Notebook Essentials: Commands & Cell Magic

Jupyter notebooks are organized in In(put) and Out(put) cells:

- **Cell Types:**

- Code: Runs Python (or other kernel)
- Markdown: For notes, explanations, LaTeX
- Raw: Plain text

- **Running Cells:**

- Shift + Enter: Run current cell, go to next
- Ctrl + Enter: Run current cell, stay
- Alt + Enter: Run current cell, insert new cell below

Kernels are the brain behind the Notebook:

- It is the **computational engine** that executes your code
- Executes code you run in cells, stores **variables**, **imports**, **functions**, maintains **state** until restarted or shut down.

Notebook Commands (Magics):

```
%time          # Time execution of a line
%%timeit       # Run cell multiple times
                # to get avg execution time
%matplotlib inline # Show plots inline
%load filename.py # Load code from
                  # file into a cell
%run script.py  # Run a full script
```

Shell-like Commands:

```
!ls          # List files in
              # current directory
!pwd         # Show current
              # working directory
!pip list    # Show installed
              # Python packages
```

Jupyter Keyboard Shortcuts: Command Mode vs. Edit Mode

Modes:

- Edit mode (green border):
Press Enter to type/edit a cell
- Command mode (blue border):
Press Esc to manage cells

Help Tips:

H	Open all shortcut keys menu
Tab	Autocomplete
Shift + Tab	Quick help on a function
?function_name	Open docstring of function

Command Mode Shortcuts:

A	Insert cell above
B	Insert cell below
D D	Delete cell
Z	Undo cell deletion
Y	Change to code cell
M	Change to Markdown cell
Shift+M	Merge selected cells
0 0	Restart the kernel

The End of Interlude

Python VirgoTools Overview

PythonVirgoTools is a suite of Python functions and classes designed to interact with the Virgo interferometer's software, hardware, and data. Widely used in the control room, calibration, and DetChar.

Main Capabilities:

- Frame file access: read channel data (`getChannel`, `FrameFile.get_frame`)
- Interferometer control: send/receive Cm messages to other processes (`cm_send`, `cm_start`)
- DSP (digital signal processor) interface: get/set parameters of suspension DSPs
- Configuration file parsing: read `.cfg` files and extract structured control parameters

Python VirgoTools Modules & Use Cases

Key Modules:

- gpstime: Time conversions between GPS, UTC, and Europe/Rome local time
- frame_lib: Access and iterate Virgo frame files (.gwf, .ffl) for channel data
- cm_lib: Interface with Virgo Cm messaging system to send commands
- interface_DSP: Read and write values from suspension DSPs with smooth ramping
- cfg_lib: Extract structured info from .cfg control files
- vpm: Query VirgoProcessMonitoring XML for real-time status

Code Example: Read recent IMC transmission data

```
x = getChannel('raw', 'INJ_IMC_TRA_DC', now_gps() - 3600, 10)

# Visualize with matplotlib
plt.plot(x.time, x.data)
plt.show()
```
